

Philosophy of QM 24.111

Second lecture,
7 Feb. 2005

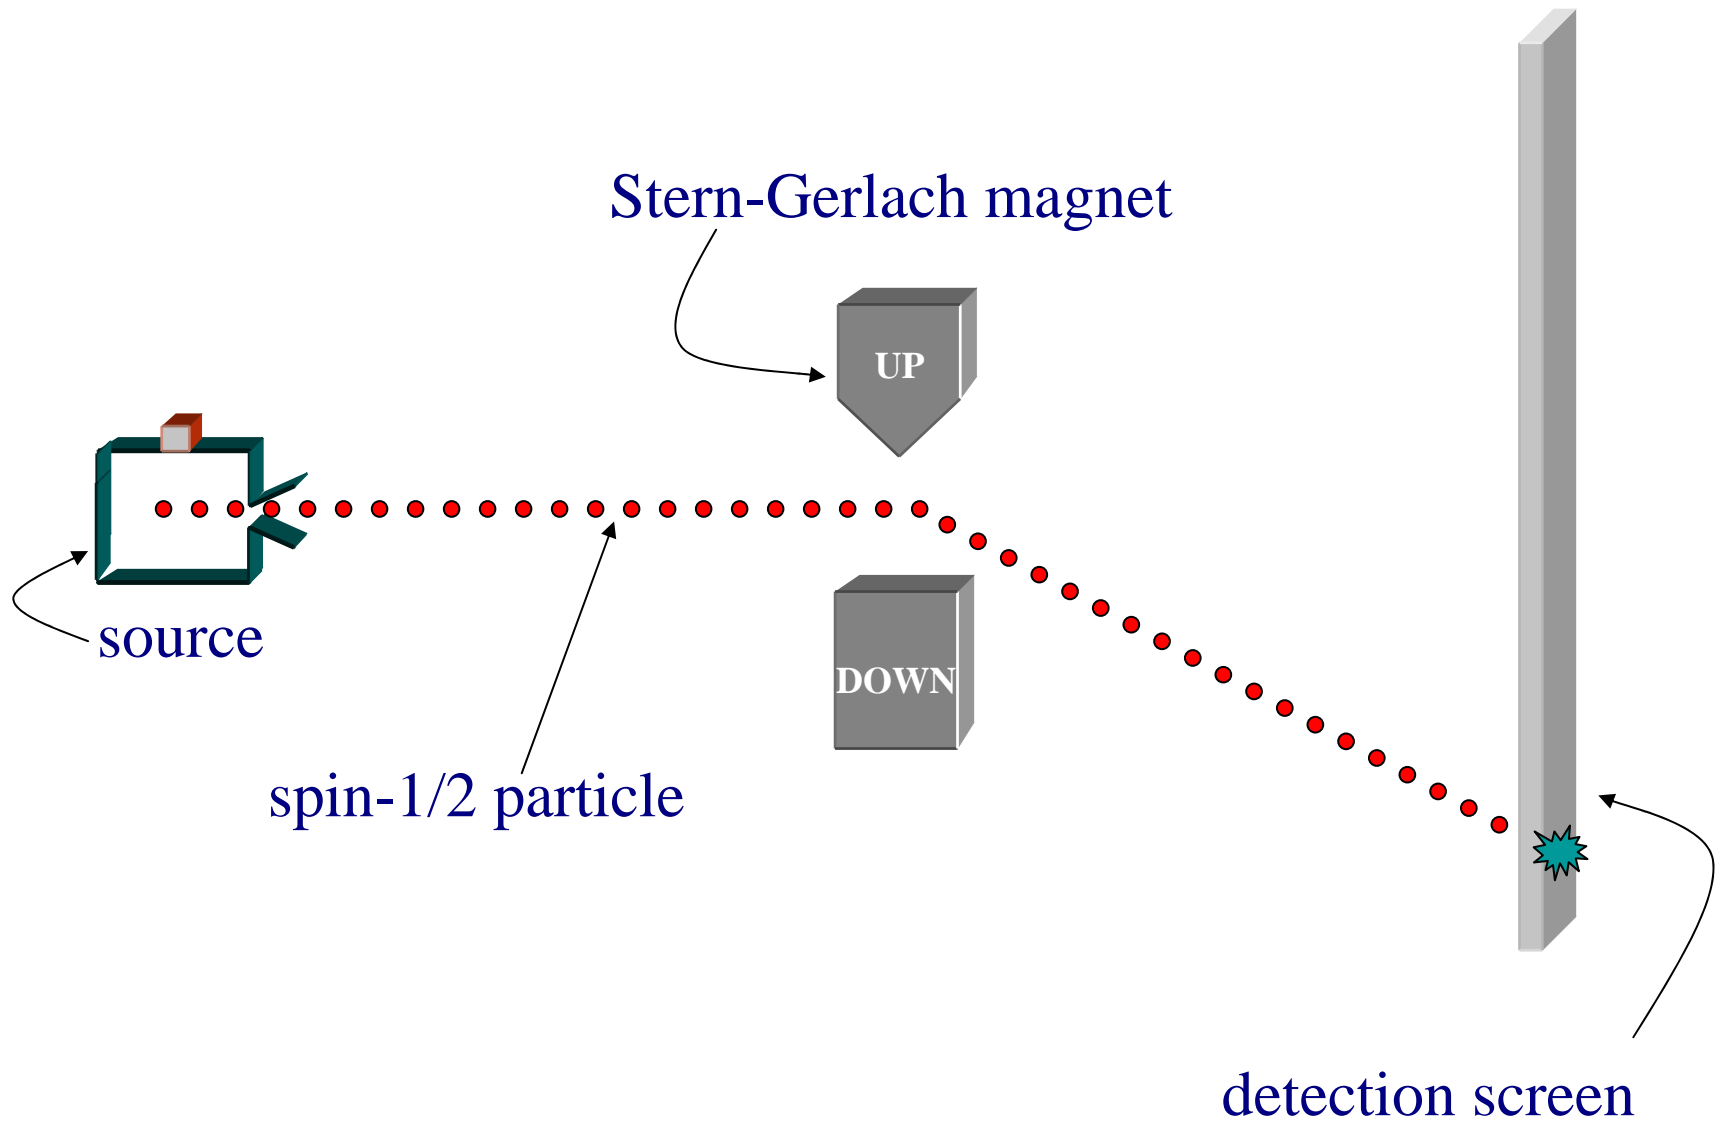

THE BASIC EXPERIMENT:

THE BASIC EXPERIMENT:

THE BASIC EXPERIMENT:

We can change the magnet orientation to any angle from 0° to 360° ; the outcomes are still “up” and “down”.

orientation = θ°

orientation = θ°

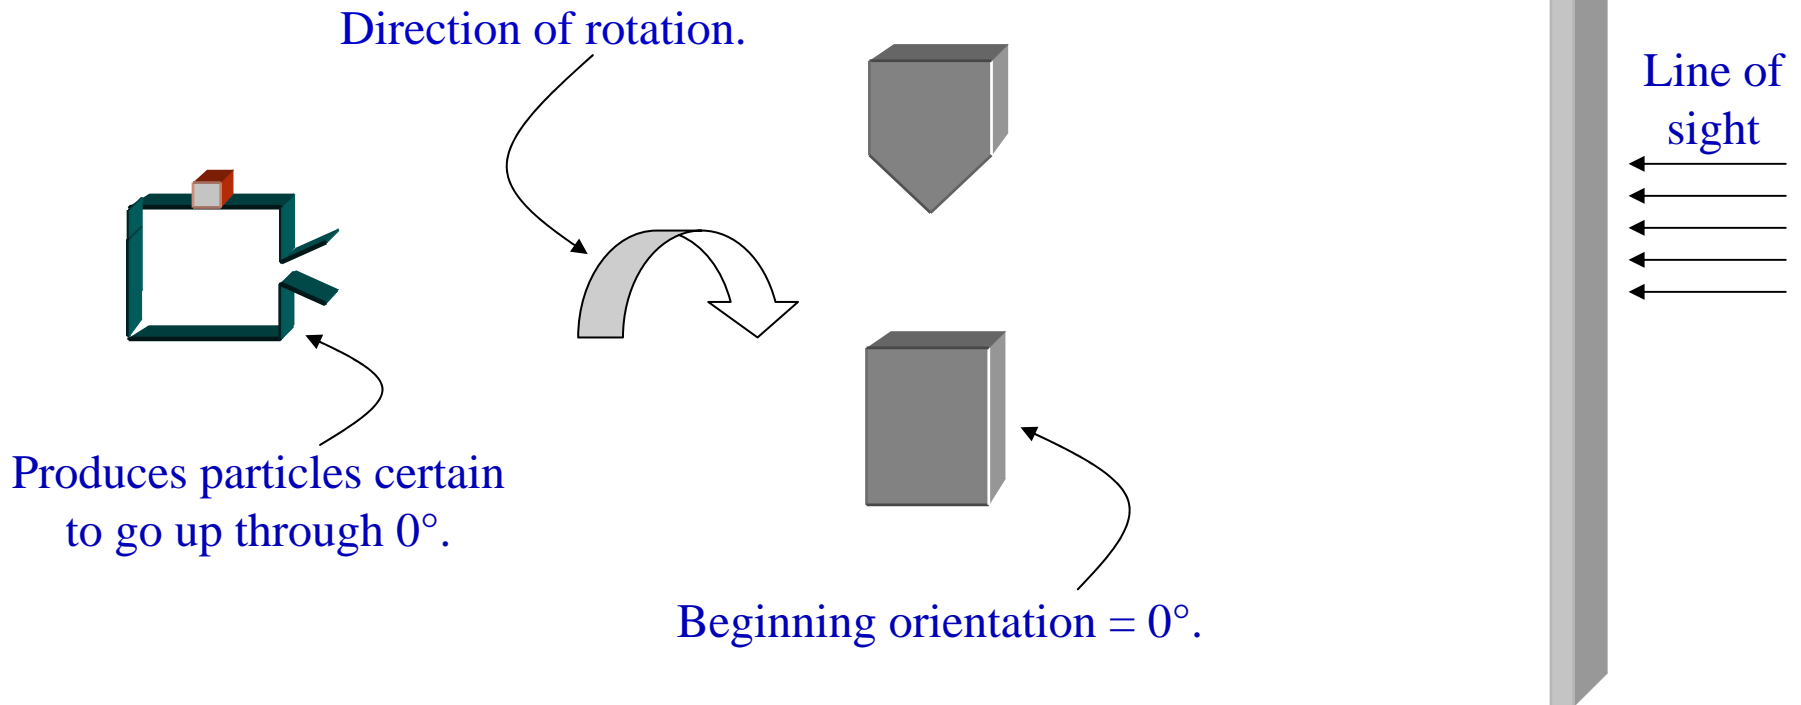

orientation = θ°

Particles passed through magnets with the *same* orientation travel in the *same* direction.

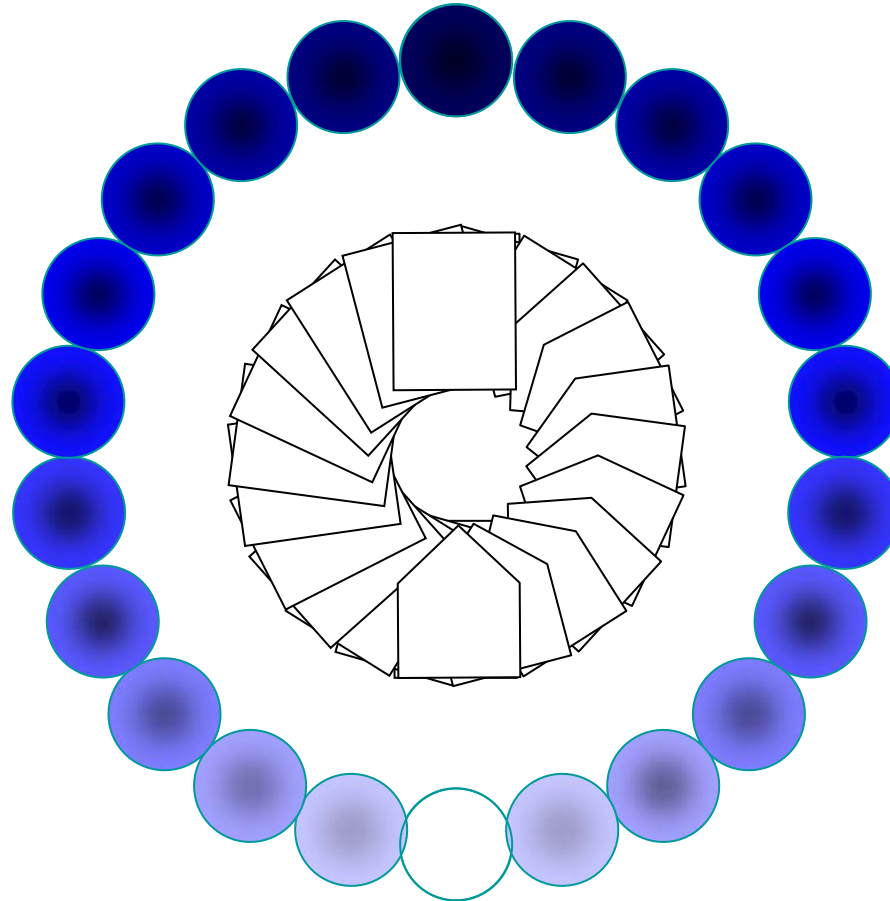

So, for any orientation magnet we choose, we can design a source that will produce particles *certain* to go up through a magnet with that orientation. **What happens when we send such particles through magnets with *different* orientations?**

WHAT WE SEE:

WHAT WE SEE:

WHAT WE SEE CONFORMS TO THE FOLLOWING LAW:

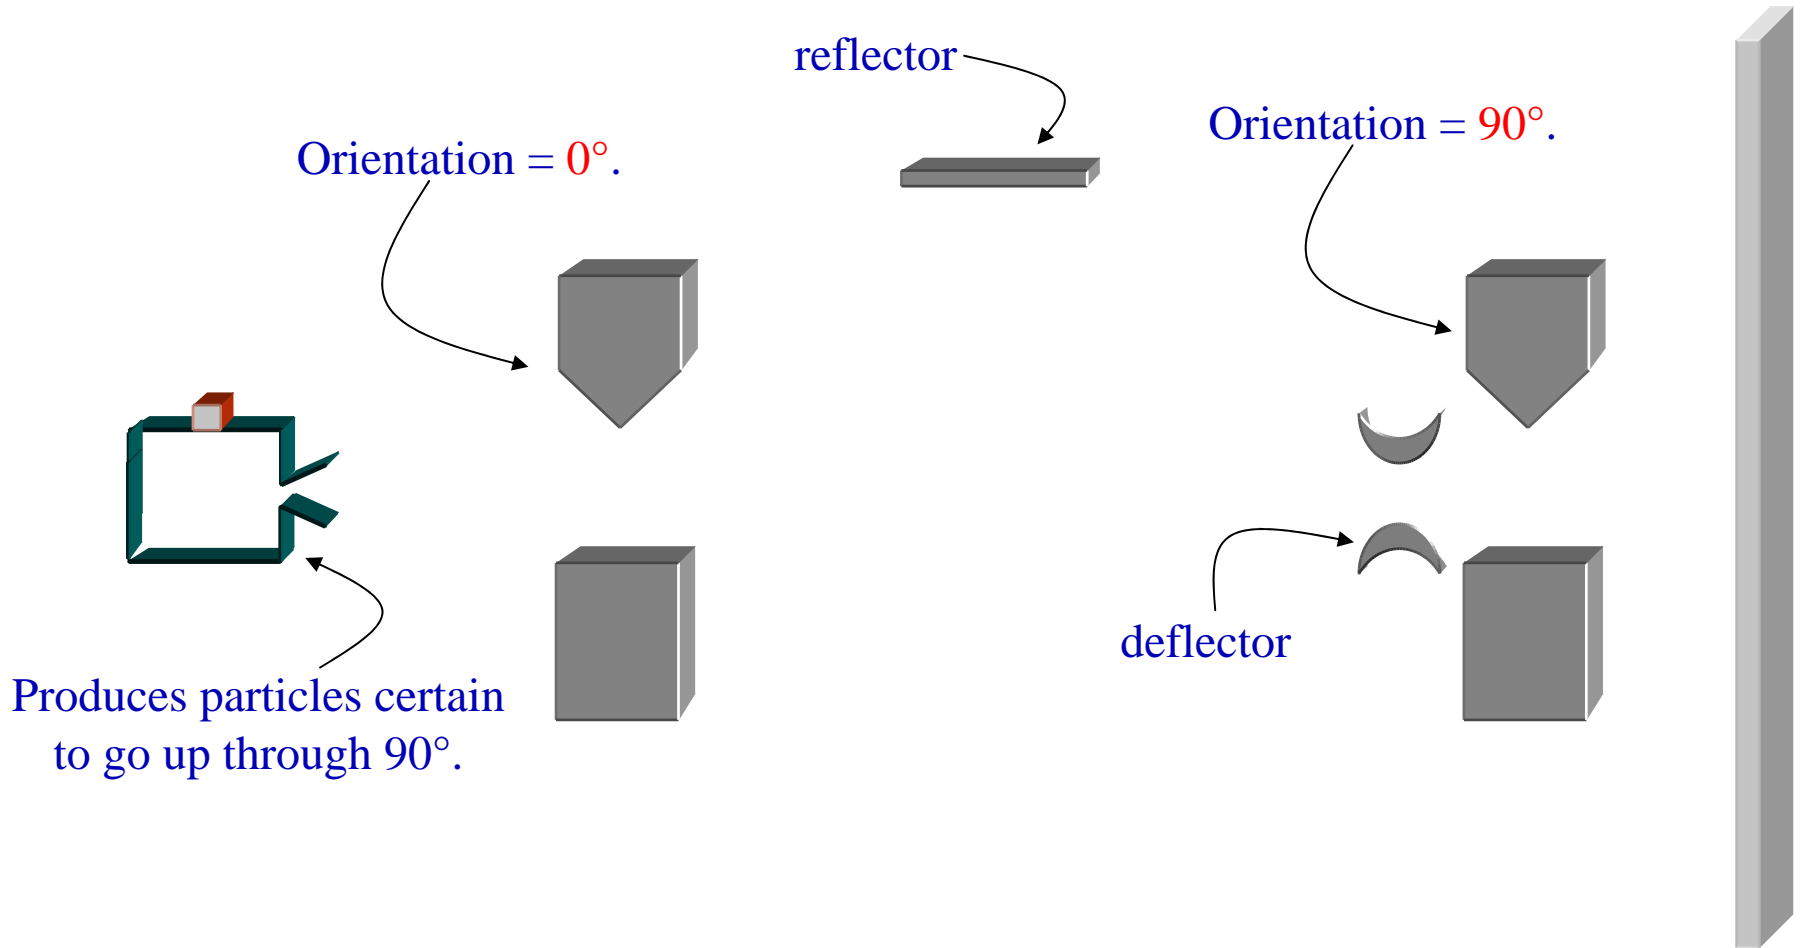

If a particle is certain to go up through a magnet with orientation θ_1 , then its probability for going up through a magnet with orientation θ_2 is

$$\cos^2\left(\frac{\theta_1 - \theta_2}{2}\right)$$

(Quantum mechanics, incidentally, predicts this “cos-squared law” exactly.)

Note that both of our “laws” hold with ‘up’ replaced by ‘down’.

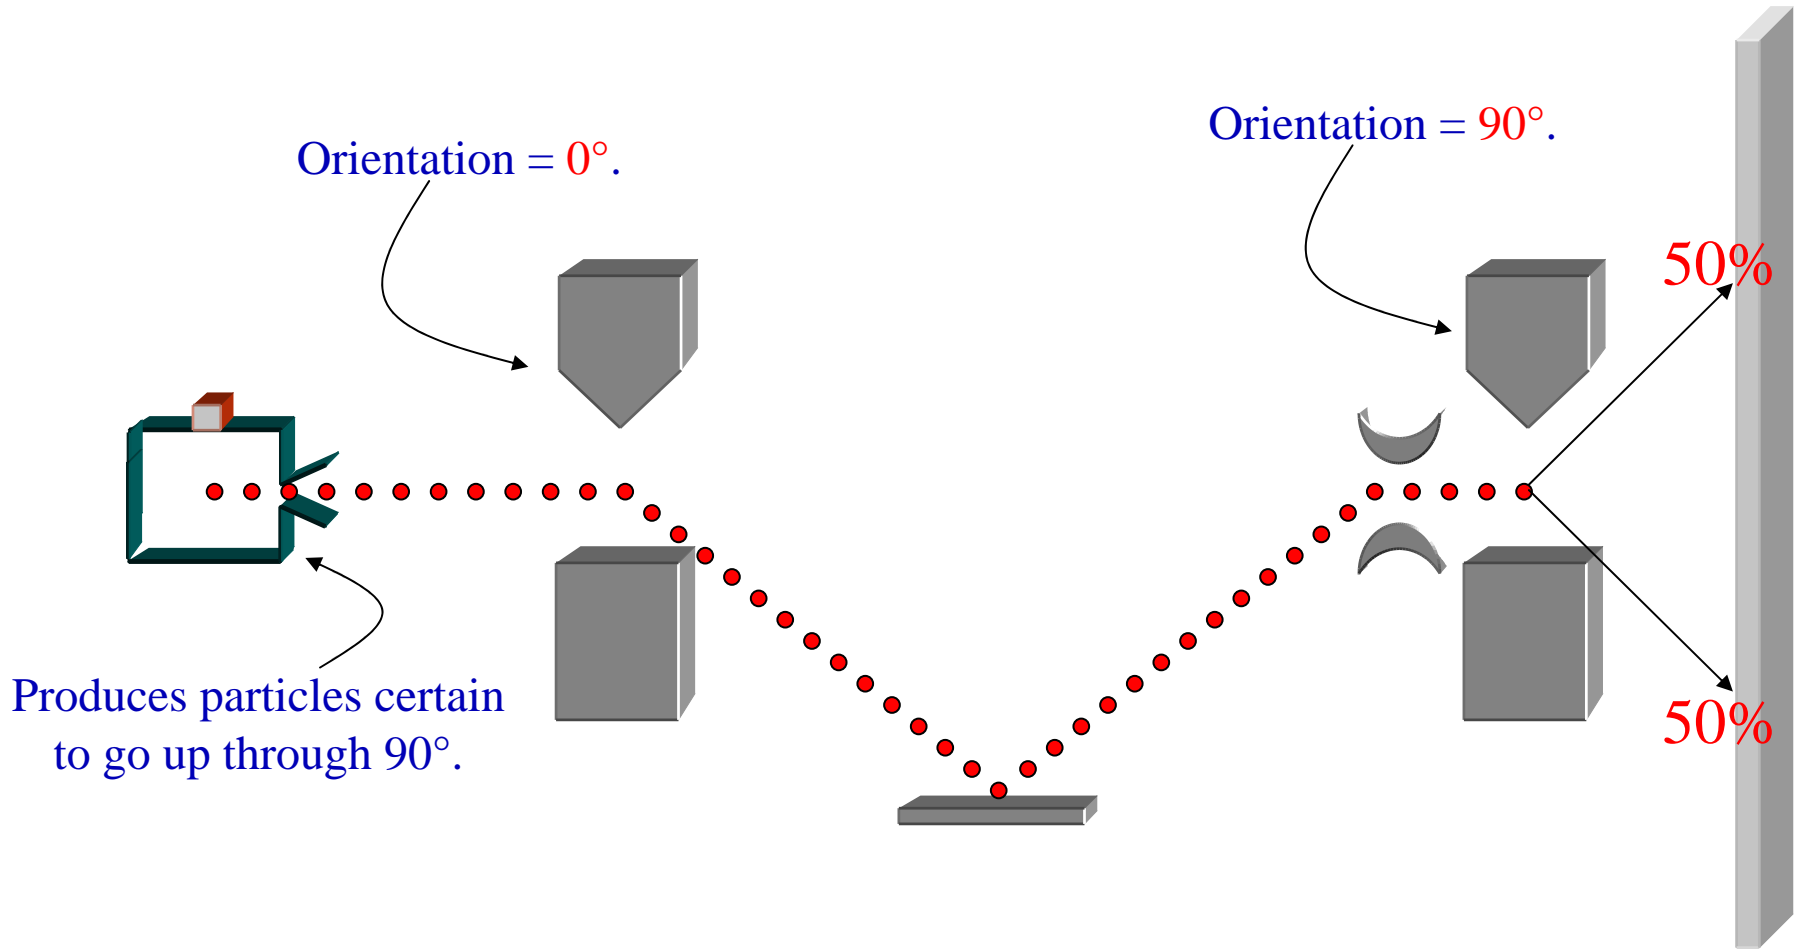

THE TWO-PATH EXPERIMENT:

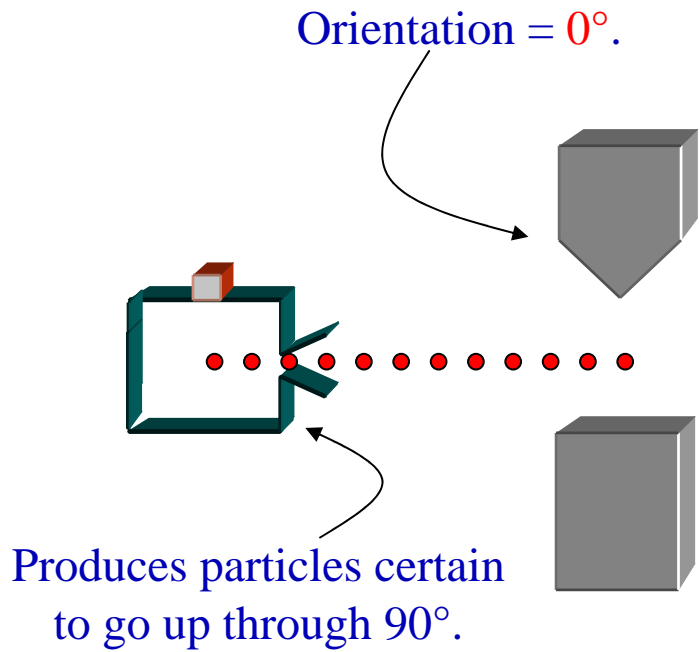

THE TWO-PATH EXPERIMENT:
