

Course information

- Negative Polarity Items and related phenomena
- Presentation and final paper

Plan for today

- Entailment and entailment-reversal
- The Condition: environments vs. operators
- Case studies: Interfering non-monotone quantifiers; so-called negated DPs

An initial paradigm

Any has a more restricted distribution than certain other determiners (say, *a*, *every*).

- (1) a. Mary did *(not) read any book.
b. Mary {*often/rarely} read any book.
- (2) Every student who read any book ate (*any) chocolate.

Some other expressions have more or less the same distribution as *any*, say, (*even*) *a single book*, though this comes apart in some environments (e.g., the restrictor of *every*)

- (3) %Every student who read (even) a single book ate chocolate.

Yet other expressions have more or less the opposite distribution, say, *almost every*, though complementarity may not hold in all environments (e.g., the restrictor of *every*, where both *any* and *almost every* are acceptable; cf. Spector 2014)

- (4) a. Mary did (*not) read almost every book.
b. Mary {often/*rarely} read almost every book.
- (5) Every student who read almost every book ate chocolate.

Standard tasks

- Provide a descriptive generalization of when an *any*-DP is acceptable.
- Provide an explanation of this generalization.

(We will focus primarily on *any* in the course. See below for some discussion of *almost*.)

Getting at the relevant representations

Existential vs. universal quantification (e.g., esp., Ladusaw 1979)

- (6) a. Candidate 1: $\llbracket \text{any} \rrbracket = \llbracket a \rrbracket = \lambda P. \lambda Q. \exists x (P(x) \wedge Q(x))$
 b. Candidate 2: $\llbracket \text{any} \rrbracket = \llbracket \text{every}^* \rrbracket = \lambda P. \lambda Q. \forall x (P(x) \rightarrow Q(x))$
- (7) John didn't read any book.
 a. Candidate 1: $\llbracket \text{neg} \llbracket \text{any book} \rrbracket \llbracket \lambda x \llbracket \text{John read } x \rrbracket \rrbracket \rrbracket$
 b. Candidate 2: $\llbracket \text{every}^* \text{ book} \rrbracket \llbracket \lambda x \llbracket \text{neg} \llbracket \text{John read } x \rrbracket \rrbracket \rrbracket$
- (8) a. Fact: for all P, $\neg \exists x Px \leftrightarrow \forall x \neg Px$
 b. Candidate 1 \Leftrightarrow Candidate 2
- (9) Every student who read any book ate chocolate.
 a. Candidate 1: $\llbracket \text{every} \llbracket \text{student} \llbracket \lambda x \llbracket \text{any book} \rrbracket \llbracket \lambda y \llbracket x \text{ read } y \rrbracket \rrbracket \rrbracket \llbracket \text{ate chocolate} \rrbracket \rrbracket$
 b. Candidate 2: $\llbracket \text{every}^* \text{ book} \rrbracket \llbracket \lambda y \llbracket \text{every} \llbracket \text{student} \llbracket \lambda x \llbracket x \text{ read } y \rrbracket \rrbracket \rrbracket \llbracket \text{ate chocolate} \rrbracket \rrbracket$
- (10) a. Fact: for all P, q, where x is not free in q, $(\exists x (Px)) \rightarrow q \leftrightarrow \forall x (Px \rightarrow q)$
 b. Candidate 1 \Leftrightarrow Candidate 2

Other quantifiers: rarely

- (11) John rarely read any book.
- (12) a. $\llbracket \text{rarely}_C \llbracket \text{any book} \rrbracket \llbracket \lambda x \llbracket \text{John read } x \rrbracket \rrbracket \rrbracket$
 b. $\llbracket \text{every}^* \text{ book} \rrbracket \llbracket \lambda x \llbracket \text{rarely}_C \llbracket \text{John read } x \rrbracket \rrbracket \rrbracket$
- (13) $\text{card}(\{t \in C \mid \exists x (\text{book } x \wedge \text{John read } x \text{ at } t)\}) < d_{st}$ (observed)
 $\stackrel{\Rightarrow}{\neq} \forall x (x \text{ is a book} \rightarrow (\text{card}(\{t \in C \mid \text{John read } x \text{ at } t\}) < d_{st}))$ (not observed)

But perhaps *rarely* decomposes (= *usually not*; *pace* Ladusaw 1979):

- (14) $\llbracket \text{usually}_C \llbracket \text{every}^* \text{ book} \rrbracket \llbracket \lambda x \llbracket \text{not} \llbracket \text{John read } x \rrbracket \rrbracket \rrbracket \rrbracket$

Other quantifiers: fewer than 5 boys

- (15) Fewer than 5 students read any book.
- (16) $\text{card}(\lambda x. \text{student } x \wedge \exists y (\text{book } y \wedge x \text{ read } y)) < 5$ (observed)
 $\stackrel{\Rightarrow}{\neq} \forall y (\text{book } y \rightarrow \text{card}(\lambda x. \text{student } x \wedge x \text{ read } y) < 5)$ (not observed)

Decomposition does not obviously help here (cf., e.g., Hackl 2000; Heim 2008).

Trapping effects

- (17) Fewer than 10 presidents_{*i*} read any books about themselves_{*i*}.
- (18) John didn't want to marry any plumber. [de dicto]
- (19) There isn't any book here. [definiteness effect]

Further support for the relevance of the LF (cf., e.g., Progovac 1994)

- (20) A professor with any interest is not available.
- (21) a. A professor with any interest seemed not to be available.
b. *A professor with any interest_{*i*} seemed to herself_{*i*} not to be available.
- (22) a. [seem [not [[a professor with any interest] be available]]
b. *[a professor with any interest] λx [x seem to herself_{*x*} [not x be available]]
- (23) A professor with any interest seemed to fewer than 5 students to be available.
- (24) a. [seem to fewer than 5 students [[a prof with any interest] be available]]
b. *[a prof with any interest] λx [x seem to fewer than 5 students [x be avail.]]

Some attention to surface form is needed nonetheless:

- (25) *Any professor seemed not to be available. (e.g., Uribe-Etxebarria 1995)

Another issue: interaction with Quantifier Raising

- (26) $\langle * \rangle$ A professor with any interest (seemed to have) read fewer than 5 books.

Better example (by Danny Fox, due to a potential confound involving the limited scope interactions of indefinites with certain other quantifiers, raised by Keny Chatain):

- (27) a. A flag with stripes is hanging from fewer than 5 windows.
b. *A flag with any stripes is hanging from fewer than 5 windows.

The Condition: Schema

- (28) a. LF: [OP [... any ...] ...]
b. OP \in {neg, every, fewer than 5, fewer than 5 students}

- (29) **The Condition** (schema, holds at LF):
 A DP headed by *any* is acceptable if and only if **it** stands in relation **R** to **X**.

The Condition: Negative, Affective, etc., Operators

- (30) a. **R** = be c-commanded by
 b. **X** = negation

Finding negation (cf. discussion of *rarely*, *fewer than 5 students* above)

- (31) a. [every student VP] = [[NOT [SOME_N student]] VP]
 b. [[NOT]] = $\lambda Q_{((et)t)}. \lambda P_{(et)}. \neg Q(P)$
 c. [[SOME_N]] = $\lambda P_{(et)}. \lambda Q_{(et)}. \exists x(Px \wedge \neg Qx)$
- (32) a. [NOT [SOME_N student who read any book]] [ate chocolate]
 b. *[NOT [SOME_N student]] [ate any chocolate]

But a parallel analysis can be provided for *some*. A more adequate predictor is needed.

Entailment-reversal

- (33) a. John read a book.
 b. $\not\Leftarrow$ John read a (Russian) book (slowly).
- (34) a. John did not read a book.
 b. \Rightarrow John did not read a (Russian) book (slowly).
- (35) a. John often read a book.
 b. $\not\Leftarrow$ John often read a (Russian) book (slowly).
- (36) a. John rarely read a book.
 b. \Rightarrow John rarely read a (Russian) book (slowly).
- (37) a. Every student read a book.
 b. $\not\Leftarrow$ Every student read a (Russian) book (slowly).
- (38) a. Every student who read a book ate chocolate.
 b. \Rightarrow Every student who read a (Russian) book (slowly) ate chocolate.

How to capitalize on this suggestive pattern?

Operators

Cross-categorical definition of entailment (\Rightarrow)

- (39) a. For p, q of type t : $p \Rightarrow q$ iff $p = 0$ or $q = 1$.
 b. For f, g of conjoinable type $\sigma\tau$: $f \Rightarrow g$ iff for every x of type σ , $f(x) \Rightarrow g(x)$.
- (40) a. t is a conjoinable type.
 b. if τ is a conjoinable type, then for all types σ , $(\sigma\tau)$ is a conjoinable type.
- (41) a. IP: $\llbracket \text{John read a Russian book} \rrbracket \Rightarrow \llbracket \text{John read a book} \rrbracket$
 b. VP: $\lambda x. \llbracket \text{a Russian book} \rrbracket (\lambda y. x \text{ read } y) \Rightarrow \lambda x. \llbracket \text{a book} \rrbracket (\lambda y. x \text{ read } y)$
 c. DP: $\llbracket \text{a Russian book} \rrbracket \Rightarrow \llbracket \text{a book} \rrbracket$

Entailment-reversing, entailment-preserving, non-monotone functions

- (42) A function f of type $(\sigma\tau)$ is entailment-reversing (downward-entailing) iff for all x, y of conjoinable type σ : if $x \Rightarrow y$, then $f(y) \Rightarrow f(x)$.
- (43) A function f of type $(\sigma\tau)$ is entailment-preserving (upward-entailing) iff for all x, y of conjoinable type σ : if $x \Rightarrow y$, then $f(x) \Rightarrow f(y)$.
- (44) A function f of type $(\sigma\tau)$ is non-monotone iff f is neither entailment-reversing nor entailment-preserving, that is, iff for some x, y, z, u of conjoinable type σ : $x \Rightarrow y$ and $f(x) \not\Rightarrow f(y)$, and $z \Rightarrow u$ and $f(u) \not\Rightarrow f(z)$.

Illustrations

- (45) $\llbracket \text{not} \rrbracket$ is entailment-reversing. (modus tollens)
 For all p, q of type t , if $p \Rightarrow q$, then $\llbracket \text{not} \rrbracket (q) \Rightarrow \llbracket \text{not} \rrbracket (p)$.
- (46) $\llbracket \text{every} \rrbracket$ is entailment-reversing. (transitivity)
 For all P, Q, R of type (et) , if $P \Rightarrow Q$, then $\llbracket \text{every} \rrbracket (Q)(R) \Rightarrow \llbracket \text{every} \rrbracket (P)(R)$.
- (47) $\llbracket \text{every student} \rrbracket$ is not entailment-reversing.
 $\llbracket \text{every student} \rrbracket (\llbracket \text{arrived} \rrbracket) \not\Rightarrow \llbracket \text{every student} \rrbracket (\llbracket \text{arrived early} \rrbracket)$
- (48) $\llbracket \text{every student} \rrbracket$ is entailment-preserving. (transitivity)
 For all P, Q, R of type (et) , if $P \Rightarrow Q$, then $\llbracket \text{every} \rrbracket (R)(P) \Rightarrow \llbracket \text{every} \rrbracket (R)(Q)$.
- (49) $\llbracket \text{between 4 and 8 students} \rrbracket$ is non-monotone.
 $\llbracket \text{between 4 and 8 students} \rrbracket (\lambda x. \llbracket \text{a Russian book} \rrbracket (\lambda y. x \text{ read } y))$
 $\not\Rightarrow \llbracket \text{between 4 and 8 students} \rrbracket (\lambda x. \llbracket \text{a book} \rrbracket (\lambda y. x \text{ read } y))$

- (50) **The Condition** (preliminary, operator-based)
 A DP headed by *any* is acceptable if and only if **it is c-commanded** by an expression that denotes an **entailment-reversing (ER) function**.

The Condition: Entailment-Reversing Environments

Entailment-reversing environments

Function-based (or position-based) statement (cf. Homer 2008)

- (51) A constituent C is ER with respect to a subconstituent Q of type σ iff λx_{σ} . $\llbracket C[Q/t_{\sigma}] \rrbracket^{g[t \rightarrow x]}$ is an ER function. (A constituent $C[Q/t_{\sigma}]$ is identical to C except that Q is replaced by a variable t of the same type as Q .)

Substitution-based statement (cf. Gajewski 2011)

- (52) A constituent C is ER with respect to a subconstituent Q iff for every Q' such that $\llbracket Q' \rrbracket \Rightarrow \llbracket Q \rrbracket$, $\llbracket C \rrbracket \Rightarrow \llbracket C[Q/Q'] \rrbracket$. (A constituent $C[Q/Q']$ is identical to C except that Q is replaced by Q' .)

Illustration

- (53) $\llbracket \llbracket_{DP} \text{every student } [\lambda x [\text{any book } [\lambda y [x \text{ read } y]]]] \rrbracket \rrbracket$ is ER wrt *any book*.
- (54) $\llbracket \llbracket_S [\text{every student } [\lambda x [\text{any book } [\lambda y [x \text{ read } y]]]] \text{ arrived}] \rrbracket \rrbracket$ is ER wrt *any book*.

- (55) **The Condition** (preliminary, environment-based)
 A DP headed by *any* is acceptable if and only if **it is dominated by a constituent that is ER with respect to it**.

What's coming up next?

- Do the two conditions have to be further constrained?
 - Do we need to admit a constraint pertaining to locality? For this, we will look at the effects of embedded non-monotone quantifiers.

- Are there any restrictions on what the constituent has to be in the case of the environment-based characterization? For this, but mainly as a warm-up for next section, we will probe the behavior of *any* (and *almost*) in structures with so-called negated DPs.
- What is the relation between the two characterizations of the Condition?
 - Are the two statements of the Condition (or their updated variants) distinguishable? Are they independent? For this, we will first investigate the distribution of *any* in the scope of modified numeral quantifiers. (We will also get at the above question by doing that.)

Non-monotonicity: a tentative argument for environments?

- (56) Mary didn't point between 4 and 8 recruiters to any students.
- (57) a. *[neg [between 4 and 8 rec's [λy any students λx Mary point y to x]]
 b. [neg [any students [λx between 4 and 8 rec's [Mary point y to x]]]
- (58) Distinguishing scenarios:
- a. Mary pointed to each of her 3 students 2 recruiters (that is, altogether 6 recruiters were pointed to students). (57-a) ✗, (57-b) ✓; (56) <✓>
- b. Mary pointed to each of her 3 students 5 recruiters (that is, altogether 15 recruiters were pointed to students). (57-a) ✓, (57-b) ✗; (56) <✗>

Contrast with sentences in which movement is blocked:

- (59) *Mary didn't introduce between 4 and 8 students_{*i*} to any of their_{*i*} partners.

This is expected on the environment-based Condition:

- (60) [[(57-a)] is not, but [[(57-b)] is, ER with respect to *any books*.

But it is not expected on the operator-based Condition:

- (61) [not] c-commands [any book] in both (57-a) and (57-b).

A modification of the operator-based characterization is needed. For example (we will ignore the modification until we get to intervention):

- (62) **The Condition** (revised, preliminary)
 A DP headed by *any* is acceptable if and only if it is c-commanded by an ER operator that doesn't c-command an NM operator that would c-command *any*.

Important caveat. These facts perhaps only apparently advantage the environment-based approach. Consider the following sentence:

- (63) She didn't wear any earrings to every party. (Linebarger, 1987)
- (64) a. [not [any earrings λx [she wore x to every party]]]
 b. *[not [[any earrings λx she wore x] to every party]]
 c. [every party λy [not [any earrings λx she wore x to y]]]
- (65) [I think that to every party she wore a different pair of earrings, and it is common knowledge that she wore earrings to at least one party:]
 <#>I doubt that she didn't wear any earrings to every party.
- (66) a. *She didn't introduce every person_i to any of their_i admirers.
 b. *Not every student read any book.

Accordingly, the assumption that will capture this state of affairs may well subsume the facts with non-monotone quantifiers. Stay tuned (and check Chierchia 2013).

So-called negated DPs: identifying licensing environments

See, e.g., Collins 2017a,b for some recent discussion.

- (67) Not every student who read any book arrived.
- (68) Candidate structures:
 a. *[[_{DP} [_D not every] student [wh λx [any book] λy x read y]] arrived]
 b. [[_{DP} not [_{DP} every student [wh λx [any book] λy x read y]]] arrived]
 c. [_S not [_S [every student [wh λx [any book] λy x read y]] arrived]]

Unavailable parse

- (69) [[not every]] = $\lambda P.\lambda Q. \neg \forall x(P(x) \rightarrow Q(x))$
- (70) a. [[not every]] is not an ER function.
 b. [[not every] student [wh λx [any book] λy x read y]] ([arrived]) is not ER with respect to [any book].

Available parses

- (71) [[every]] is an ER function.
- (72) [every student [wh λx [any book] λy x read y]] is ER wrt [any book]:
 For all Q, $Q \Rightarrow$ [[any/a book],
 [[every student [λx [any book] λy x read y]]]]

$$\Rightarrow \llbracket \text{every student } [\lambda x Q \lambda y x \text{ read } y] \rrbracket$$

That is,

For all Q and R, $Q \Rightarrow \llbracket \text{any/a book} \rrbracket$,

$$\llbracket \text{every student } [\lambda x [\text{any book}] \lambda y x \text{ read } y] \rrbracket (R)$$

$$\Rightarrow \llbracket \text{every student } [\lambda x Q \lambda y x \text{ read } y] \rrbracket (R)$$

(And, therefore, $\llbracket \text{every student } [\text{wh } \lambda x [\text{any book}] \lambda y x \text{ read } y] \rrbracket$ arrived)

is also ER wrt $\llbracket \text{any book} \rrbracket$.)

What about negated modified numeral quantifiers?

(73) $\langle \rangle$ Not fewer than 5 students read any book.

(74) Candidate structures (no decomposition of the modified numeral):

a. $*\llbracket \text{not fewer than 5} \rrbracket \text{ students} \llbracket \lambda x [\text{any book}] \lambda y [x \text{ read } y] \rrbracket$

b. $*\llbracket \text{not } [\text{fewer than 5 students}] \rrbracket \llbracket \lambda x [\text{any book}] \lambda y [x \text{ read } y] \rrbracket$

c. $\llbracket \text{not } \llbracket \text{fewer than 5 students} \rrbracket \llbracket \lambda x [\text{any book}] \lambda y [x \text{ read } y] \rrbracket$

Could *not* end up being in a configuration resembling that in (74-c) by movement – one on which we have two ER operators c-commanding *any book*? To get at this question, compare (73) with (75):

(75) $\langle ?* \rangle$ No fewer than 5 students read any book.

Finally, note that the reverse may be expected if we had an expression whose distribution under (non-auxiliary) negation and *fewer than* quantifiers were the reverse of that of *any*. (A DP-internal construal of *no* may be needed in (77).)

(76) $\langle * \rangle$ Not fewer than five students almost arrived.

(77) $\langle \rangle$ No fewer than five students almost arrived.
